## Report Summary

Powdery mildew is caused by the biotrophic fungus *Erysiphe necator* (1); this polycyclic disease of grape causes losses to crop quality and yield and is considered one of the most economically important disease of grapes worldwide. This report details the findings of our annual powdery mildew fungicide trials on grapevine (*Vitis vinifera*, Cultivar Chardonnay on 5C – 30- yrs-old). Along with Muscat blanc, Roussanne and Carignan, Chardonnay is one of the highly susceptible wine varieties (2).

This trial was conducted at Trinchero Family Estates Vineyards, Elk Grove (38°19'14.2"N, -121°30'25.7"W) from April to July 2020. Treatments were placed in a complete randomized block design. Spraying commenced on April 15<sup>th</sup>. Spraying was completed at veraison on July 24<sup>th</sup>, and treatments were evaluated for disease incidence and severity on August 4<sup>th</sup> 2020.

The trials consisted of soft chemistry products and synthetic fungicides. Spray frequencies varied from 7 day to 21-day intervals.

## Materials and Methods

### A. Experimental design

**Table 1. Experimental design**

Experimental design	Randomized complete block design with 5 replicates		
Experimental unit	2 adjacent vines = 1 plot		
Row and tree spacing	15 ft (row) and 6 ft (vine)	Plot unit area	90 ft <sup>2</sup>
Area/treatment	450 ft <sup>2</sup> or 0.01033 acre/treatment (5 replicates = 1 treatment)		
Volume water/Acre	50 gallons (pre-bloom to pea-sized berries) = 1.0352 gal/5 reps 100 gallons (late April,) = 2.0704 gal/5 reps, 150 gallons (late May) = 3.1056 gal/5 reps		
Equipment	Stihl SR 450 Backpack Sprayers		

## B. Experimental treatments

The treatments described in this report were conducted for experimental purposes only and crops treated in a similar manner may not be suitable for commercial or other use.

## E. Vine Management

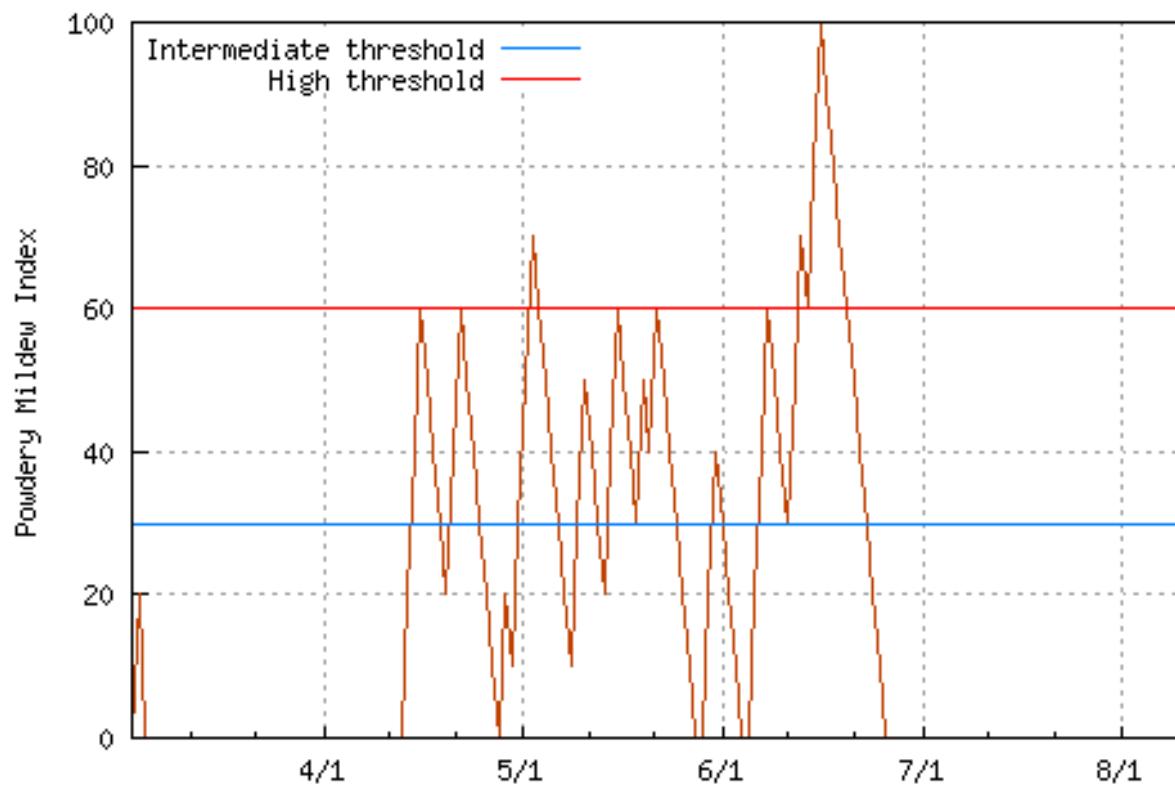

During the application period, vines were irrigated by drip irrigation. Sucker shoot removal and leafing were done during the duration of trial.

## F. Data Collection and Statistics

Daily temperature and relative humidity were obtained from the trial site in Elk Grove (Figure 1). Powdery mildew incidence and severity were assessed in each treatment by evaluating twenty-five random clusters. Incidence was defined as the proportion of clusters in a plot having some living powdery mildew. Severity was determined by estimating the percentage of area of a cluster that was infected; the severity value of all clusters was then averaged to give a plot-wide estimate of disease severity. Mean incidence and severity values for each treatment were computed. Trial models were analyzed using the ANOVA Tests for data. Means comparisons were made using Fisher's LSD with  $\alpha=0.05$ .

**Figure 1.** Average daily relative humidity (%RH), average daily temperature (°C) and number of grape powdery mildew spore counts were recorded from April 2020 to August 2020.

**Figure 2.** Thomas-Gubler Risk Index data from March to August. The Red line data points indicate risk index > 60, between blue and red data points indicate risk index data between 30 and 60 and blue data points are values below 30.

## Results

**Table 1.** Disease incidence and severity. Product names are followed by rate (per acre) and the frequency of application. Treatment means followed by the same letter are not significantly different according to Fisher's LSD at  $\alpha=0.05$ ; /= followed by.
